# Impossible Differential Cryptanalysis

## Setup

top  $P[\Delta_{in} \rightarrow \Delta_X] = 2^{-c_{in}}$

middle  $P[\Delta_X \rightarrow \Delta_Y] = 0$

bottom  $P[\Delta_{out} \rightarrow \Delta_Y] = 2^{-c_{out}}$

## Main idea

If a candidate key partially encrypts/decrypts a given pair to an impossible differential then this key is wrong.

## Early Abort Technique Algorithm

Let  $k_1, k_2, \dots, k_b$  be key bits  $k_{in} \cup k_{out}$  and  $\sigma$  a permutation.

### Early abort

- ▶ Discard pairs which cannot follow the impossible differential
- ▶ Guess  $k_{\sigma(1)}$
- ▶ Partially encrypt/decrypt pairs and discard pairs which cannot follow the impossible differential
- ▶ Guess  $k_{\sigma(2)}$
- ⋮
- ▶ Guess  $k_{\sigma(b)}$
- ▶ Partially encrypt/decrypt pairs and discard pairs which cannot follow the impossible differential
- ▶ If all pairs have been discarded then perform an exhaustive search over remaining key bits.

## Early Abort Technique Algorithm

### Early abort without final exhaustive search - complexity

$$T_\sigma \geq \sum_{1 \leq i \leq b} 2^{|k_{\sigma(1)} \cup \dots \cup k_{\sigma(i)}| - \sum_{1 \leq j < i} r_j^\sigma} \cdot N \cdot C'_E$$

- ▶  $N$ : number of pairs
- ▶  $r_i^\sigma$ : proportion of pairs discarded at step  $i$
- ▶  $C'_E$ : ratio of the cost of partial encryption to full encryption

## Early Abort Technique Algorithm

### Early abort without final exhaustive search - complexity

$$T_\sigma \geq \sum_{1 \leq i \leq b} 2^{|k_{\sigma(1)} \cup \dots \cup k_{\sigma(i)}| - \sum_{1 \leq j < i} r_j^\sigma} \cdot N \cdot C'_E$$

- ▶  $N$ : number of pairs
- ▶  $r_i^\sigma$ : proportion of pairs discarded at step  $i$
- ▶  $C'_E$ : ratio of the cost of partial encryption to full encryption

Boura et al's assumption (ASIACRYPT 2014):

$$\min_{\sigma} T_\sigma \approx (1 + 2^{|k_{in} \cup k_{out}| - c_{in} - c_{out}}) \cdot N \cdot C'_E$$

## Outline for section 2

- 1 Introduction
  - Impossible Differential Attacks
  - Early Abort Technique
- 2 Toy Examples
  - Description of Toy Cipher
  - Complexity of Impossible Differential Attacks
- 3 Application to TWINE
  - Description of TWINE-128
  - Impossible Attack against 25-round TWINE-128
  - Computing Real Time Complexity
- 4 Conclusion

# Toy Cipher

- ▶ First round based on AES

How key schedule relations do affect time complexity?

# Independent Subkeys

- ▶  $k_0, k_5, k_{10}$  and  $k_{15}$  independent
- ▶ Boura et al's formula:

$$(1 + 2^{|k_{in}| - c_{in}}) \cdot N \cdot C'_E = (1 + 2^{32-24}) \cdot N \cdot 4S_E^{-1} \approx 2^{10} \cdot N \cdot S_E^{-1}$$

## Independent Subkeys

Early abort technique:

- ▶ Guess  $k_0$  and keep only pairs for which transitions  $\Delta_{x_5} \rightarrow \Delta_{y_5}$ ,  $\Delta_{x_{10}} \rightarrow \Delta_{y_{10}}$  and  $\Delta_{x_{15}} \rightarrow \Delta_{y_{15}}$  are possible
- ▶ Guess  $k_5$  and keep only pairs satisfying  $\Delta_{x_5} \rightarrow \Delta_{y_5}$
- ▶ Guess  $k_{10}$  and keep only pairs satisfying  $\Delta_{x_{10}} \rightarrow \Delta_{y_{10}}$
- ▶ Guess  $k_{15}$  and keep only pairs satisfying  $\Delta_{x_{15}} \rightarrow \Delta_{y_{15}}$

Real complexity:

$$(2^8 + 2^{8+8-3} + 2^{8+8+8-3-7} + 2^{8+8+8+8-3-7-7}) \cdot N \cdot S_E^{-1} \approx 2^{15.8} \cdot N \cdot S_E^{-1}$$

## Independent Subkeys

- ▶  $k_0, k_5, k_{10}$  and  $k_{15}$  independent
- ▶ Boura et al's formula:

$$(1 + 2^{|k_{in}| - c_{in}}) \cdot N \cdot C'_E = (1 + 2^{32-24}) \cdot N \cdot 4S_E^{-1} \approx 2^{10} \cdot N \cdot S_E^{-1}$$

- ▶ Real complexity:

$$(2^8 + 2^{8+8-3} + 2^{8+8+8-3-7} + 2^{8+8+8+8-3-7-7}) \cdot N \cdot S_E^{-1} \approx 2^{15.8} \cdot N \cdot S_E^{-1}$$

## Related Subkeys I

- ▶ one key schedule equation:  $k_0 = k_5$
- ▶ Boura et al's formula:

$$(1 + 2^{|k_{in}| - c_{in}}) \cdot N \cdot C'_E = (1 + 2^{24-24}) \cdot N \cdot 4S_E^{-1} = 2^3 \cdot N \cdot S_E^{-1}$$

- ▶ Real complexity:

$$(2^8 + 2^{8-3} + 2^{8+8-3-7} + 2^{8+8+8-3-7-7}) \cdot N \cdot S_E^{-1} \approx 2^{8.9} \cdot N \cdot S_E^{-1}$$

## Related Subkeys II

- ▶ one key schedule equation:  $k_0 \oplus k_5 \oplus k_{10} \oplus k_{15} = 0$
- ▶ Boura et al's formula:

$$(1 + 2^{|k_{in}| - c_{in}}) \cdot NC'_E = (1 + 2^{24-24}) \cdot N \cdot 4S_E^{-1} = 2^3 \cdot N \cdot S_E^{-1}$$

- ▶ Real complexity:

$$(2^8 + 2^{8+8-3} + 2^{8+8+8-3-7} + 2^{8+8+8-3-7-7}) \cdot N \cdot S_E^{-1} \approx 2^{14.6} \cdot N \cdot S_E^{-1}$$

## Outline for section 3

- 1 Introduction
  - Impossible Differential Attacks
  - Early Abort Technique
- 2 Toy Examples
  - Description of Toy Cipher
  - Complexity of Impossible Differential Attacks
- 3 Application to TWINE
  - Description of TWINE-128
  - Impossible Attack against 25-round TWINE-128
  - Computing Real Time Complexity
- 4 Conclusion

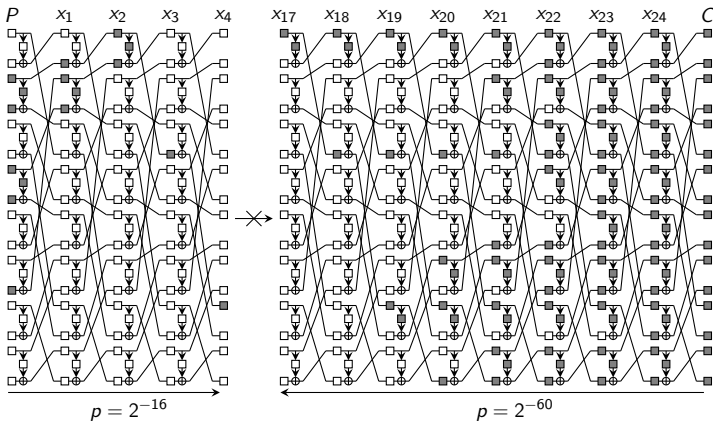

## TWINE

- ▶ Nibble-oriented Feistel
- ▶ state size: 64 bits (16 4-bit branches)
- ▶ 2 key sizes: 64 and 128 bits

# Biryukov et al's attack (FSE 2015)

- ▶ 52 subkey nibbles involved but only  $2^{124}$  possible values

## Methodology

- ▶ 52 subkey nibbles involved  $\rightarrow 52! \approx 2^{225}$  orders for the early abort technique

## Methodology

- ▶ 52 subkey nibbles involved  $\rightarrow 52! \approx 2^{225}$  orders for the early abort technique

If between two guesses no pairs are discarded then the order in which they are guessed does not matter.

When do pairs are discarded?

## Discarding pairs

Proportion of pairs:

- ▶  $\Delta x, \Delta y$ : probability of transition  $\Delta x \rightarrow \Delta y \approx 2^{-1}$
- ▶  $\Delta x, \Delta y, x \oplus k$ :  $2^{-4}$

## Exhausting Early Abort Technique

▶ Biryukov *et al*'s attack:

- ▶ 19 tuples  $(x, y, z)$   
→ 19 tuples  $(\Delta x, \Delta y) + 19$  tuples  $(\Delta x, \Delta y, x \oplus k)$
- ▶ Easy to determine corresponding subkey nibbles
- ▶ But brute force still infeasible:

$$(19 + 19)! = 38! \approx 2^{148}$$

## Exhausting Early Abort Technique

▶ Biryukov et al's attack:

- ▶ 19 tuples  $(x, y, z)$   
→ 19 tuples  $(\Delta x, \Delta y)$  + 19 tuples  $(\Delta x, \Delta y, x \oplus k)$
- ▶ Easy to determine corresponding subkey nibbles
- ▶ But brute force still infeasible:

$$(19 + 19)! = 38! \approx 2^{148}$$

▶ Search:

- ▶  $K_i \subseteq K_j \Rightarrow$  guess  $K_i$  before  $K_j$
- ▶ Generic formula:

$$\text{Best}(K_1, \dots) = \min_i (\text{Best}(K_1, \dots, K_{i-1}, K_{i+1}, \dots) + 2^{|K_1 \cup \dots| - \sum_{j \neq i} r(K_j)})$$

## Exhausting Early Abort Technique

▶ Biryukov et al's attack:

- ▶ 19 tuples  $(x, y, z)$   
→ 19 tuples  $(\Delta x, \Delta y) + 19$  tuples  $(\Delta x, \Delta y, x \oplus k)$
- ▶ Easy to determine corresponding subkey nibbles
- ▶ But brute force still infeasible:

$$(19 + 19)! = 38! \approx 2^{148}$$

▶ Search:

- ▶  $K_i \subseteq K_j \Rightarrow$  guess  $K_i$  before  $K_j$
- ▶ Generic formula:

$$\text{Best}(K_1, \dots) = \min_i (\text{Best}(K_1, \dots, K_{i-1}, K_{i+1}, \dots) + 2^{|K_1 \cup \dots| - \sum_{j \neq i} r(K_j)})$$

How to compute  $2^{|K_1 \cup \dots|}$  ?

## TWINE-128 Key Schedule

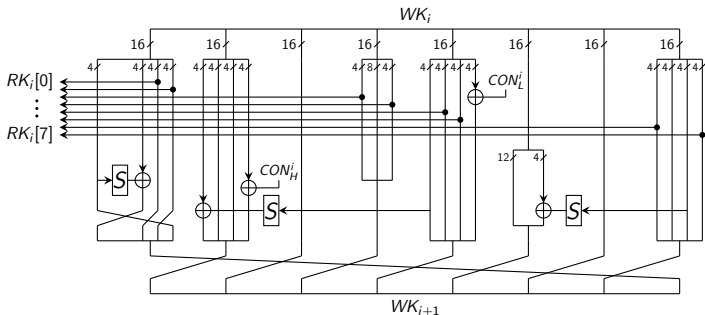

- Shape of key schedule equations:

$$\bigoplus \alpha_i k_i \oplus \beta_i S(k_i) = \gamma,$$

where  $\alpha_i$ 's,  $\beta_i$ 's and  $\gamma$  are constant

## TWINE-128 Key Schedule

- Shape of key schedule equations:

$$\bigoplus \alpha_i k_i \oplus \beta_i S(k_i) = \gamma,$$

where  $\alpha_i$ 's,  $\beta_i$ 's and  $\gamma$  are constant

- Use Derbez *et al*'s tool (FSE 2013)

## Result

- ▶ Computation of real complexity: 1h on personal computer
- ▶ Result:

$$\min_{\sigma} T_{\sigma} \geq 2^{54} \cdot N_{\alpha} \cdot C_{E'}$$

- ▶ Time complexity of whole attack higher than:

$$C_{N_{\alpha}} + \alpha \cdot 2^{127.6} + 2^{128-\alpha}$$

- ▶ Higher than  $2^{128}$  for all  $\alpha > 0$ .

## Outline for section 4

- 1 Introduction
  - Impossible Differential Attacks
  - Early Abort Technique
- 2 Toy Examples
  - Description of Toy Cipher
  - Complexity of Impossible Differential Attacks
- 3 Application to TWINE
  - Description of TWINE-128
  - Impossible Attack against 25-round TWINE-128
  - Computing Real Time Complexity
- 4 Conclusion

## Conclusion

### In this paper:

- ▶ Boura *et al*'s formula too optimistic
  - ▶ reaching it is, if not impossible, very tricky
- ▶ Construction of simple counter-examples:  
→ deviation up to a factor  $2^{11.6}$
- ▶ Algorithm computing real complexity for TWINE
  - ▶ complexity of Biryukov *et al*'s attack higher than  $2^{128}$
  - ▶ applicable to more ciphers

### Open problems:

- ▶ Improve the formula
- ▶ Find an example with time complexity smaller than expected

## Thanks

Thank you for your attention!
